Hyperprolactinaemia - a guide for GPs

Definition

Prolactin > 700 mIU/L on a single sample without excessive venepuncture stress, at any time of day in both males and females is considered clinically significant hyperprolactinaemia and requires further investigation.

Note: The cut off of 700 mIU/L is a clinical action threshold and not a reference range. If a patient has symptoms of hyperprolactinaemia below this cut off, advise discussion with the Duty Biochemist (01225 824050)

Prolactin (mIU/L)	Interpretation
700 - 2000	Mild hyperprolactinaemia
2000 - 5000	Significant hyperprolactinaemia
>5000	Severe hyperprolactinaemia

Symptoms of hyperprolactinaemia

In females

- Oligomenorrhoea/amenorrhoea
- Galactorrhoea (when not pregnant or breast feeding)
- Vaginal dryness
- Acne
- Hirsutism

In males

- Erectile dysfunction
- Decreased body and facial hair
- Gynaecomastia

In both sexes

- Low bone density
- Reduction in other pituitary hormone production
- Decreased libido
- Headaches
- Visual disturbances
- Infertility

In children

Ref.: PATH 026

- Growth failure
- Delayed puberty

Causes of Hyperprolactinaemia

Factitious causes of hyperprolactinaemia

Macroprolactin – Biologically inactive immunoglobulin-bound-prolactin (macroprolactin) can cross react in the prolactin assay causing false hyperprolactinaemia. The laboratory will routinely screen for macroprolactin on every first raised (>700 IU/L) prolactin seen in an individual patient. The presence of macroprolactin is not pathological itself; if present, an estimation of bioactive prolactin is reported with interpretation to guide further investigations.

Physiological causes of hyperprolactinaemia

Pregnancy – measurement of prolactin during pregnancy is not routinely indicated or required

Breastfeeding - measurement of prolactin during breastfeeding is not routinely indicated or required

Exercise

Stress (physical or psychological, including venepuncture)

Sleep

Post-ictal (within hours of a seizure)

Neonatal period

Chest wall surgery or trauma

Medication induced hyperprolactinaemia can be associated with the following:

TRH

High dose oestrogens

Antipsychotic drugs: phenothiazines (e.g. chlorpromazine, promazine, thioridazine, sulpiride, fluphenazine, trifluoperazine), haloperidol, flupentixol, risperidone, paliperidone

Selective serotonin reuptake inhibitors (citalopram, fluoxetine, fluvoxamine, sertraline, paroxetine)

Antiemetics (metoclopramide, domperidone)

Cardiovascular drugs (verapamil, reserpine, methyldopa)

Opiates, opioids (transient, rare)

Monoamine oxidase inhibitors

Cimetidine (intravenous)

Verapamil

Liquorice

Miscellaneous (bezafibrate, omeprazole, trimethoprim, histamine H2 antagonists)

Tricyclic antidepressants (rare)

Pathological causes of hyperprolactinaemia

Pituitary tumour (prolactin secreting tumour, or non-secreting pituitary tumour that prevents dopamine reaching normal prolactin producing cells)

Hypothalamic/pituitary stalk lesion

Neuraxis irradiation

Spinal cord lesion

Head injury (e.g. due to disruption of the pituitary stalk)

Chronic renal failure (reduced prolactin clearance)

Severe liver disease (disordered hypothalamic regulation)

Primary hypothyroidism (increased synthesis of TRH)

PCOS

Investigations and Management in Primary Care

If prolactin persistently > 1000 other pituitary function tests are indicated.

Further investigations through endocrinology referral may include pituitary MRI, visual field testing and dynamic testing of anterior pituitary function.

Management

The main principle of management of hyperprolactinaemia is to identify and treat the underlying cause if feasible.

The goals of treatment are:

- Relieve symptoms (if present)
- Prevent complications from osteoporosis or pressure effects
- Restore fertility and sexual function

Patients with prolactinomas are managed by Endocrinology.

All prolactin results are clinically reviewed by the Duty Biochemist and interpretative comments appended to results to guide further investigations and when referral is indicated.

Further sources of Information

For further advice regarding hyperprolactinaemia please contact the duty biochemist on 01225 824050 Monday –Friday 9am-5pm.
